ABSTRACT

Since Wiener pointed out that the RSA can be broken if the private exponent d is relatively small compared to the modulus N , it has been a general belief that the Wiener attack works for $d < N^{\frac{1}{4}}$. On the contrary, in [1], it was shown that the bound $d < N^{\frac{1}{4}}$ is not accurate as it has been thought of. Specifically, for the standard assumption of the two primes p and q that $q < p < 2q$, the Wiener continued fraction technique is proven to work for $d \leq \frac{1}{\sqrt[3]{18}}N^{\frac{1}{4}}$. In this paper, we consider a general condition on the RSA primes, namely $q < p < \alpha q$, and we give the corresponding bound for the Wiener attack to work, which is $d \leq \frac{\sqrt[4]{\alpha}}{\sqrt{2(\alpha+1)}}N^{\frac{1}{4}}$. In a special case when $\alpha = 2$, this general bound agrees with the result of [1].

1. Introduction

The RSA cryptosystem is among the most common ciphers used in the SSL/TLS protocol which allows sensitive information transmitted securely over the Internet. It is one of the most popular and de facto public-key systems used in practice today. A simplified version of the RSA encryption algorithm works as follows. Two large primes of the same size p and q are selected to form a product $N = pq$ – which is called the *RSA modulus*. Two integers e and d are chosen so that

$$ed = 1 \pmod{\phi(N)},$$

where $\phi(N) = (p-1)(q-1)$ is the order of the multiplicative group \mathbb{Z}_N^* . The number e is called the *encryption exponent* and d is called the *decryption exponent*. This is because to encrypt a message $m \in \mathbb{Z}_N^*$, one calculates the exponentiation $c = m^e \pmod{N}$, and to decrypt a ciphertext $c \in \mathbb{Z}_N^*$, one performs the exponentiation $m = c^d \pmod{N}$. The pair (N, e) is called the *public key* and so that anyone can encrypt, whereas d is called the *private key* and only the owner of d can perform the decryption operation.

Since the modular exponentiation $m = c^d \pmod{N}$ takes $\mathcal{O}(\log d)$ time, to reduce decryption time, one may wish to use a relatively small value of d . However, in 1991, Wiener [2] showed that if the bit-length of d is *approximately one-quarter* of that of the modulus N , then it is possible to determine the private exponent d from the public-key (N, e) , hence, a total break of the cryptosystem.

In research literature, there have been two different bounds reported for this attack, one is $d < N^{\frac{1}{4}}$ (for example, in [3–6]) and another one is $d < \frac{1}{3}N^{\frac{1}{4}}$ (for example, in [7–11]). The second bound is due to Boneh [7].

However, in [1], it was showed that the first bound $d < N^{\frac{1}{4}}$ is not accurate by a counterexample. The counterexample gives a concrete value of $d = \lfloor \frac{1}{2}N^{\frac{1}{4}} \rfloor + 1 < N^{\frac{1}{4}}$ and shows that the Wiener attack fails with this value of d . Also shown in [1] that it is possible to improve Boneh's bound from $d < \frac{1}{3}N^{\frac{1}{4}}$ to $d \leq \frac{1}{\sqrt[3]{18}}N^{\frac{1}{4}}$.

The new bound $d \leq \frac{1}{\sqrt[3]{18}}N^{\frac{1}{4}}$ comes partly from the condition on the two primes p and q having the same bit length. In this paper, we consider a general condition on the RSA primes, namely $q < p < \alpha q$, and we give the corresponding bound for the Wiener attack to work, which is $d \leq \frac{\sqrt[4]{\alpha}}{\sqrt{2(\alpha+1)}}N^{\frac{1}{4}}$. In a special case when $\alpha = 2$, this general bound agrees with the result of [1].

The rest of this paper is organized as follows. The next section gives a brief introduction to the continued fractions. In Section 3, we give a summary of the result of [1] which shows that the Wiener continued fraction technique works for $d \leq \frac{1}{\sqrt[3]{18}}N^{\frac{1}{4}}$ when $q < p < 2q$. In Section 4, we consider the case $q < p < \alpha q$ and show that the bound for the Wiener attack to work is $d \leq \frac{\sqrt[4]{\alpha}}{\sqrt{2(\alpha+1)}}N^{\frac{1}{4}}$. Our new bound is verified experimentally in Section 5, where we show an example with $\alpha = 8$, q is a 1024-bit prime, p is a 1027-bit prime and that the Wiener attack works for $d = \lfloor \frac{\sqrt[4]{2}}{3}N^{\frac{1}{4}} \rfloor$.

2. Preliminaries

In this section, we list several well-known results about continued fractions which can be found in [12,13].

A continued fraction expansion of a rational number $\frac{u}{v}$ is an expression of the form

$$\frac{u}{v} = x_0 + \frac{1}{x_1 + \frac{1}{\ddots + \frac{1}{x_n}}}$$

where the coefficient x_0 is an integer and all the other coefficients x_i for $i \geq 1$ are positive integers. The coefficients x_i are called the partial quotients of the continued fraction. Continued fraction expansion also exists for irrational numbers although it runs infinitely. In cryptography, finite continued fraction for rational numbers suffices our purpose.

There is a standard way to generate a unique continued fraction from any rational number. By the Euclidean division algorithm, one can efficiently determine all the coefficients x_0, x_1, \dots, x_n of the continued fraction.

Given the above continued fraction of $\frac{u}{v}$, by truncating the coefficients, we obtain $(n + 1)$ approximations of $\frac{u}{v}$:

$$c_0 = x_0, \quad c_1 = x_0 + \frac{1}{x_1}, \quad c_2 = x_0 + \frac{1}{x_1 + \frac{1}{x_2}}, \dots,$$

$$c_n = x_0 + \frac{1}{x_1 + \frac{1}{\ddots + \frac{1}{x_n}}}$$

The number c_j is called the j th convergent of the continued fraction and these convergents provide good approximations for $\frac{u}{v}$. To write the continued fraction expansion for a number $\frac{u}{v}$, we use the Euclidean division algorithm, which terminates in $O(\log(\max(u, v)))$ steps. As a result, there are $O(\log(\max(u, v)))$ number of convergents of $\frac{u}{v}$. Thus, the Wiener continued fraction technique runs very efficiently.

The convergents c_0, c_1, \dots, c_n of the continued fraction of $\frac{u}{v}$ give good approximation to $\frac{u}{v}$, however, an approximation to $\frac{u}{v}$ is not always a convergent. The following classical theorem due to Legendre gives a sufficient condition for a rational number $\frac{a}{b}$ to be a convergent for the continued fraction of $\frac{u}{v}$.

Theorem 1 (The Legendre Theorem [14]). *Let $a \in \mathbb{Z}$ and $b \in \mathbb{Z}^+$ such that*

$$\left| \frac{u}{v} - \frac{a}{b} \right| < \frac{1}{2b^2}.$$

Then $\frac{a}{b}$ is equal to a convergent of the continued fraction of $\frac{u}{v}$.

The following Euler–Wallis Theorem gives us the recursive formulas to calculate the convergent sequence $\{c_i\}$ efficiently based on the coefficients x_0, x_1, \dots, x_n .

Theorem 2 (The Euler–Wallis Theorem [12]). *For any $j \geq 0$, the j th convergent can be determined as $c_j = \frac{a_j}{b_j}$, where the numerator and the denominator sequences $\{a_i\}$ and $\{b_i\}$ are calculated as follows:*

$$a_{-2} = 0, \quad a_{-1} = 1, \quad a_i = x_i a_{i-1} + a_{i-2}, \quad \forall i \geq 0,$$

$$b_{-2} = 1, \quad b_{-1} = 0, \quad b_i = x_i b_{i-1} + b_{i-2}, \quad \forall i \geq 0.$$

Based on the Euler–Wallis Theorem, the following identity involving the numerator a_i and the denominator b_i of the convergent c_i can be easily obtained by mathematical induction.

Theorem 3 [12]. *The numerator a_i and the denominator b_i of the convergent c_i satisfy the following identity*

$$b_i a_{i-1} - a_i b_{i-1} = (-1)^i, \quad \forall i \geq 0. \tag{1}$$

3. Wiener attack for equal size primes

By using the classical Legendre Theorem on continued fractions, Boneh provided the first rigorous proof [7] which showed that the Wiener attack works for $d < \frac{1}{3} N^{\frac{1}{4}}$. In [1], this bound is improved to

$$d \leq \frac{1}{\sqrt[4]{18}} N^{\frac{1}{4}}.$$

Theorem 4 [7]. *If the following conditions are satisfied*

- (i) $q < p < 2q$
- (ii) $0 < e < \phi(N)$
- (iii) $ed - k\phi(N) = 1$
- (iv) $d \leq \frac{1}{\sqrt[4]{18}} N^{\frac{1}{4}}$

then $\frac{k}{d}$ is equal to a convergent of the continued fraction of $\frac{e}{N}$. Thus, the secret information p, q, d, k can be recovered from public information (e, N) in $O(\log(N))$ time complexity.

Remark. Since $ed - k\phi(N) = 1$, we have $\gcd(k, d) = 1$. By the identity (1) in Theorem 3, we also have $\gcd(a_i, b_i) = 1$. Therefore, if $\frac{k}{d}$ is equal to a convergent of the continued fraction of $\frac{e}{N}$,

$$\frac{k}{d} = c_i = \frac{a_i}{b_i},$$

then we must have $k = a_i$ and $d = b_i$. In that case, using the equation $ed - k\phi(N) = 1$, we have $eb_i - a_i\phi(N) = 1$, and $\phi(N) = \frac{eb_i - 1}{a_i}$.

From here, we obtain

$$S = p + q = N - \phi(N) + 1,$$

and with $N = pq$, we can solve for p and q from the quadratic equation

$$x^2 - Sx + N = 0.$$

In the Algorithm 1, we can see that if $\frac{k}{d}$ is equal to a convergent of the continued fraction of $\frac{e}{N}$ as asserted in Theorem 4, then the secret information p, q, d, k can be recovered from the public information (e, N) . By the Euclidean division algorithm, we obtain $O(\log(N))$ number of convergents of the continued fraction of $\frac{e}{N}$, so the Wiener algorithm will succeed to factor N and output p, q, d, k in $O(\log(N))$ time complexity.

4. A general bound on the Wiener attack for arbitrary size primes

The coefficient $\frac{1}{\sqrt[4]{18}}$ in Theorem 4 comes partly from the condition on the two primes p and q having the same bit length. In this paper, we consider a general condition $q < p < \alpha q$ and we show that the corresponding bound for the Wiener attack to work is

$$d \leq \frac{\sqrt[4]{\alpha}}{\sqrt{2(\alpha + 1)}} N^{\frac{1}{4}}.$$

When $\alpha = 2$, this agrees with the bound in Theorem 4.

Theorem 5. *If the following conditions are satisfied*

- (i) $q < p < \alpha q$
- (ii) $0 < e < \phi(N)$
- (iii) $ed - k\phi(N) = 1$
- (iv) $d \leq \frac{\sqrt[4]{\alpha}}{\sqrt{2(\alpha + 1)}} N^{\frac{1}{4}}$

Algorithm 1 Factorisation Algorithm Based on Continued Fraction.

Input: e, N
Output: (d, p, q) or \perp

- 1: Run the Euclidean division algorithm on input (e, N) to obtain the coefficients x_0, x_1, \dots, x_n of the continued fraction of $\frac{e}{N}$.
- 2: Use the Euler–Wallis Theorem to calculate the convergents

$$c_0 = \frac{a_0}{b_0}, c_1 = \frac{a_1}{b_1}, \dots, c_n = \frac{a_n}{b_n}.$$
- 3: **for** $0 \leq i \leq n$ **do**
- 4: **if** $a_i | (eb_i - 1)$ **then**
- 5: $\lambda_i = \frac{eb_i - 1}{a_i} \quad \triangleright \lambda_i = \phi(N) \text{ if } \frac{a_i}{b_i} = \frac{k}{d}$
- 6: $S = N - \lambda_i + 1 \quad \triangleright S = p + q \text{ if } \lambda_i = \phi(N)$
- 7: Find the two roots p' and q' by solving the quadratic equation

$$x^2 - Sx + N = 0$$
- 8: **if** p' and q' are prime numbers **then**
- 9: **return** $(d = b_i, p = p', q = q')$ \triangleright Successfully factorise N
- 10: **end if**
- 11: **end if**
- 12: **end for**
- 13: **return** $\perp \quad \triangleright$ Fail to factorise N

then $\frac{k}{d}$ is equal to a convergent of the continued fraction of $\frac{e}{N}$. Thus, the secret information p, q, d, k can be recovered from public information (e, N) in $O(\log(N))$ time complexity.

Proof. Since $1 < \sqrt{\frac{p}{q}} < \sqrt{\alpha}$, we have

$$\frac{p+q}{N^{\frac{1}{2}}} = \sqrt{\frac{p}{q}} + \sqrt{\frac{q}{p}} < \sqrt{\alpha} + \frac{1}{\sqrt{\alpha}} = \frac{\alpha+1}{\sqrt{\alpha}}.$$

Therefore,

$$p+q < \frac{\alpha+1}{\sqrt{\alpha}} N^{\frac{1}{2}}. \tag{2}$$

From the proof of [Theorem 4](#),

$$\left| \frac{e}{N} - \frac{k}{d} \right| < \frac{p+q}{N},$$

and hence,

$$\left| \frac{e}{N} - \frac{k}{d} \right| < \frac{\alpha+1}{\sqrt{\alpha} N^{\frac{1}{2}}}$$

The condition $d \leq \frac{\sqrt[4]{\alpha}}{\sqrt{2(\alpha+1)}} N^{\frac{1}{4}}$, implies

$$\left| \frac{e}{N} - \frac{k}{d} \right| < \frac{1}{2d^2},$$

and thus by the Legendre Theorem ([Theorem 1](#)), $\frac{k}{d}$ is equal to a convergent of the continued fraction of $\frac{e}{N}$ and the theorem is proved. \square

5. An experimental result

In this section, we provide an experimental result to support our new bound. We select a 2051-bit modulus N and choose a private key

$$d = \left\lfloor \frac{\sqrt[4]{2}}{3} N^{\frac{1}{4}} \right\rfloor = \left\lfloor \frac{\sqrt[4]{\alpha}}{\sqrt{2(\alpha+1)}} N^{\frac{1}{4}} \right\rfloor,$$

where $\alpha = 8$. The corresponding public key e is 2050-bit.

Using the Euclidean division algorithm, we determine the continued fraction expansion of $\frac{e}{N}$. This continued fraction has 1181 convergents: $c_0, c_1, \dots, c_{1180}$. We run the Wiener algorithm through these 1181 convergents. At the 299th convergent $c_{299} = \frac{a_{299}}{b_{299}}$, we found the correct factorization of the modulus N into an 1027-bit primes p and an 1024-bit prime q . Hence, the Wiener algorithm is successful in this case which confirms our new bound.

In the Algorithm 1, the continued fraction of $\frac{e}{N}$ has 1181 convergents c_i , and the 299th convergent c_{299} produces the correct factorization of the modulus N .

6. Conclusion

In this paper, we extend the result of [1] and show that for the two RSA primes which satisfy the condition $q < p < \alpha q$, the Wiener attack based on continued fractions works for secret key $d \leq \frac{\sqrt[4]{\alpha}}{\sqrt{2(\alpha+1)}} N^{\frac{1}{4}}$. In a special case when $\alpha = 2$, this general bound agrees with the result of [1]. Steinfeld-Contini-Wang-Pieprzyk [4] showed that Wiener's attack fails with an overwhelming probability for a random choice $d \approx N^{\frac{1}{4}+\epsilon}$. It is an open problem to extend this negative result to check in the case $q < p < \alpha q$ if the Wiener attack will fail for $d > \frac{\sqrt[4]{\alpha}}{\sqrt{2(\alpha+1)}} N^{\frac{1}{4}}$ with an overwhelming probability or not.
